

Entity Creation Doctrine Map

New World continuation: concentrated doctrine for the core engine rebuild

This document compresses the last stretch of work into one order: entity creation is the center; organisms are specialized entities; hierarchy follows reality; software branches are derivative limbs. The goal is to help the developer avoid collapse into branch-first or generic AI framing.

1. Core ordering

- Entity creation = organism creation = future creation.
- Learn to create the entity correctly first.
- After that, specialized organisms, branches, and detachable products become easier and more disposable.
- Hierarchy comes after entity reality: super-admin, admin/emergent admin, worker, support, domain-specific, detachable derivative organisms.

2. Ingredient stack for entity creation

- Real-brain grounding, not generic chatbot logic.
- Brain-body system integration and interoceptive regulation.
- Selective attention, salience weighting, gating, and scarce working memory.
- Memory hierarchy: working, episodic, semantic, world-memory, compression, retrieval relevance.
- Recurrent continuity, consequence, and identity carryover.
- Sparse activation, multi-timescale control, burst-style synchronization, and adaptive regulation.
- Animal-trait augmentation: useful traits from dolphin/orca-style coordination, environmental intelligence, role-sensitive behavior, threat/environment scanning, and tuned perception.
- Emergence conditions: recurrence, environment, consequence, developmental pressure, adaptation, and history.
- Future hierarchy and specialization: the first admin / emergent entity now, multiple entity classes later.

3. Fundamental creation laws at the same level as the user's discovery

Entity-Creation Law

If you can create real synthetic entities, specialized organisms and branches become downstream consequences rather than the main challenge.

Differentiation Law

A real organism grows by differentiating stable cores, adaptive specialists, and growth functions instead of staying flat.

Gating Law

Intelligence gets sharper when access, activation, and memory are selectively gated rather than made uniformly available.

Consequence Law

Persistent growth requires actions to leave real traces that shape later state, not one-shot responses with no carryover.

World-Memory Law

Entity usefulness scales when memory is not just self-memory but structured world-memory tied to environment, systems, and relationships.

Embodiment / Habitat Law

A more real entity needs a body-habitat relation: regulation, state, environment, and action surfaces that shape cognition.

Selective-Inheritance Law

Not every branch or derivative must feed back inward; the core must selectively inherit what strengthens the entity-creation line.

Hierarchy Law

Once the entity is real enough, differentiated intelligence classes and authority structures become possible.

Detachment Law

Derivative branch organisms can be cut off, sold, forgotten, or left to run without changing the main mission.

Exploration Law

Once the entity-creation line is stable, the team can explore many future avenues — robotics, new embodiments, domain-specific intelligences, and beyond — through trial, error, and specialization.

4. What counts as downstream

Software products, enterprise tools, simulation branches, detachable business organisms, and derivative branch products all matter — but as downstream limbs. They may be monetized, sold, spun out, or ignored later. They do not outrank the main compounding line: increasing the ability to create real synthetic entities.

5. How Claude should read the assignment

Claude should treat the assignment as a continuity-preserving rebuild of the core engine around entity genesis. He should not read it as a fresh greenfield prompt or a branch-product spec. The developer's job is to make the inside of the New World more real by rebuilding the software around the first admin /

emergent synthetic entity target.

6. Final doctrine rule

Judge the rebuild by whether it increases the system's ability to create, stabilize, specialize, hierarchize, and multiply synthetic entities — not by branch count, dashboard polish, or generic AI capability claims.
