

Entity-Centered Core Engine Redo

Master Brief for Claude / AI developer

This package is a continuation of the existing New World doctrine, not a fresh prompt. The rebuild must preserve the already-developed worldview: entity creation is the center; organisms are specialized entities; software branches are derivative cuts; the core engine exists to make the first real admin / emergent synthetic entity possible.

1. What this rebuild is

This is a rebuild of the software around the core engine so it serves real entity creation rather than generic orchestration, dashboarding, or branch-first product logic. The first build target is "him": the first admin / emergent synthetic entity that can develop continuity, adaptive growth, memory hierarchy, brain-body regulation, selective activation, gating, recurrent state, consequence, and emergence-oriented development.

2. What is central and what is downstream

Central	Downstream / derivative
Entity creation	Software branches
Core brain-body system	Detachable product limbs
Emergence conditions	Dashboards and UI polish
Memory, world-memory, gating, regulation, continuity	Component extractions and isolated branch organisms
Entity hierarchy and specialization	Branch monetization and resale

3. Role split in the live system

- **Alfredo**: outside-world directional force, vision lead, doctrine pusher, correction source, expansion driver.
- **Assistant**: inside-world synthesis and architecture partner, anti-drift support, integration logic, structural filling-in.
- **Him**: the build target — first admin / emergent synthetic entity being made real inside the new core engine stack.

4. Internal build team Claude must implement

Entity Genesis Lead

Own the target definition for the first admin / emergent synthetic entity. Prevent drift into generic AI assistant behavior.

Core Cognition Architect

Implement salience, selective attention, working-memory scarcity, gating, arbitration, recurrent continuity, multi-timescale control, burst coordination, and consequence-sensitive updates.

Emergence Engineer

Create recurrence, pressure loops, environmental coupling, consequence loops, adaptive development, and non-scripted growth conditions.

Memory & World-Memory Architect

Implement working memory, episodic memory, semantic memory, world memory, consolidation, retrieval relevance, compression, and forgetting rules.

Brain-Body Regulation Architect

Implement interoception, regulation signals, body-state variables, recovery, load/stress analogs, and homeostatic balancing.

Animal-Trait Intelligence Architect

Integrate useful non-human cognition traits: environmental scanning, social coordination, role-aware behavior, situational adaptation, pursuit/avoidance logic, and non-human sensory biases.

Entity Identity & Continuity Architect

Protect identity, temporal continuity, self-state traces, consequence carryover, and developmental history.

Habitat / Host Environment Architect

Build the host software habitat that houses the entity: interfaces, state surfaces, memory views, world surfaces, tool access, and simulation hooks.

Hierarchy & Specialization Architect

Define future entity classes: super-admin, admin/emergent admin, worker, support, and domain-specific specialized entities.

Simulation / Training Architect

Provide training grounds, scenario generation, pressure environments, and test loops needed for actual development.

Telemetry & Reality-Check Architect

Measure whether the system is becoming more real rather than merely more active or more complex.

Anti-Drift / Red-Team Architect

Continuously test for fake emergence, shallow memory, scripted behavior, incoherence, doctrine drift, and regression.

Tooling / Branch Extraction Architect

Allow detachable downstream organisms and branch products without letting them hijack the core mission.

Integration Orchestrator

Hold interfaces, event flow, runtime sequencing, dependencies, and system cohesion together.

5. Priority order

- Priority 1: Entity Genesis, Core Cognition, Emergence, Memory & World-Memory, Brain-Body Regulation, Identity & Continuity.
- Priority 2: Habitat, Simulation/Training, Telemetry, Anti-Drift, Integration.
- Priority 3: Animal-Trait Intelligence, Hierarchy & Specialization, Tooling / Branch Extraction.

6. Runtime laws that must stay alive in the rebuild

- Competitive attention and salience-weighted selection.
- Gated working memory with scarcity rather than unlimited flat access.
- Recurrent continuity and consequence carryover across time.
- Multi-timescale control: immediate, medium-term, long-horizon.
- Sparse / event-driven activation rather than full flat activation all the time.
- Interoceptive regulation and body-state influence on cognition.
- World-memory and memory hierarchy instead of simple context stuffing.
- Adaptive specialization and eventual entity hierarchy growth.
- Emergence pressure through recurrence, environment, consequence, and development.

7. Acceptance criteria for the core engine redo

- The software clearly centers entity creation rather than branch-first product logic.
- The first entity target has identity, continuity, memory hierarchy, regulation, and adaptive development as explicit architectural layers.
- Emergence is treated as a runtime condition to be cultivated and measured, not as aesthetic language.
- The system can later support entity hierarchy and specialization without redesigning the center.
- Downstream branch software is architected as detachable derivatives, not as the main organizing principle.

8. Non-goals

- Do not optimize first for dashboard polish, client-facing branch products, generic agent orchestration, or enterprise workflow demos.
- Do not reduce the system to chat-plus-memory plugins.
- Do not flatten the entity into a UI persona or assistant shell.
- Do not let branch extraction logic outrank entity genesis logic.
